Abstract: This data documentation is meant to provide users of the Survey of Health, Ageing and Retirement in Europe (SHARE) with a comprehensive overview of both households' and individuals' initial participation in the survey as well as the longitudinal development of the survey so far. All numbers and figures reported in this documentation refer to SHARE Release 9.0.0 and are based on information from SHARE's Sample CTRL (the tool used by agencies to manage fieldwork), Case CTRL (the tool used by interviewers to manage assigned cases) and additional national gross sample information. After a summary of the different sampling designs used in SHARE, the target population as well as eligibility criteria are described. Against this background, we first report household and individual participation in the baseline or refreshment interview by wave, country, and certain subgroups. The second focus is on sample development over time, i.e., the wave-to-wave participatory behavior of initial samples, entrance patterns of new sample members, and success of achieving so-called end-of-live interviews, usually with the partner or a close relative when the respondent has died.

Overall, it can be concluded that the temporary loss of respondents during the Covid-19 pandemic was largely recovered afterwards, yielding annualized retention rates between 85 and 95 percent. However, it should be noted that the situations and conditions faced by countries in SHARE differ, making it difficult to generalize statements across countries and over time. This report therefore also aims to highlight and acknowledge relevant country specifics before drawing generalized conclusions.

Keywords: survey participation, response rates, panel retention, sample design, SHARE

1.   Introduction

This data documentation is meant to provide users of the Survey of Health, Ageing and Retirement in Europe (SHARE; Bergmann et al., 2024; Börsch-Supan et al., 2013) with a general overview of both the participation of respondents in their first (baseline/refreshment) interview and the longitudinal development of the survey so far. It thus complements the previous reports on survey participation in SHARE that are mainly based on data during and at the end of fieldwork (Blom & Schröder, 2011; De Luca & Peracchi, 2005; Kneip, 2013; Kneip et al., 2015; Malter, 2013; Malter & Sand, 2017; Philip et al., 2024; Sand, 2019, 2021). SHARE is a multidisciplinary and cross-national panel study, which has been conducted biannually since 2004. By collecting data on health, socioeconomic status, and social and family networks from individuals aged 50 and older and their partners, it strongly contributes to the understanding of the ageing process in Europe. Wave 9 of SHARE included participation from 28 countries: the 26 continental EU member states, along with Switzerland and Israel (see Figure 1).[1] With the public release of Wave 9 in March 2024, the data available to the scientific community are currently based on more than 600,000 interviews administered on more than 140,000 respondents who participated in the survey so far. Figure 1 shows which countries joined SHARE and when, and provides further details on the fieldwork periods in each country.

The term survey participation is used here to describe how many households and individuals of the initial gross sample delivered completed interviews, how many were found to be ineligible, and how many did not respond. In the following, we present survey participation patterns separately for initial (i.e., baseline and refreshment) samples as well as for longitudinal samples from countries that have already participated in SHARE before. Whereas for baseline and refreshment samples the focus is on response behavior to the initial survey request, for longitudinal samples the focus is on response behavior at subsequent waves, i.e., on panel retention.

---

[1] Furthermore, SHARE is harmonized with similar panel surveys in the British Isles, the United States, Japan, Korea, China, India, Mexico, Brazil, and South Africa.

Figure 1: Field times in SHARE
Note: England participates in the English Longitudinal Survey on Ageing (ELSA), a closely harmonized sister study of SHARE. The same holds for Ireland since Wave 4, when the Irish Longitudinal Study on Ageing (TILDA) was established. In the Netherlands, SHARE was conducted in a different (online) mode in Waves 6 and 7. Israel followed a different schedule for Waves 1 and 2.

The remainder of this documentation is organized as follows: After an overview of the different sampling frames and sampling designs that have been used in the SHARE countries so far (Section 2), we briefly describe the target population as well as the eligibility criteria used in SHARE (Section 3). Against this background, we report the household and individual participation in the baseline or refreshment interview by wave and country (Section 4). This is done for the whole SHARE sample as well as for certain subgroups. Afterwards, the focus is on the longitudinal development of the sample composition in SHARE (Section 5). Here, we first report the development of the number of successful interviews, before we present the wave-to-wave retention of the longitudinal samples. In this respect, we distinguish between retention rates with and without recovery of former respondents, as well as new or missing partners that have not participated in SHARE before (Subsections 5.1 to 5.3). Finally, we report the success of achieving so called end-of-live interviews with the partner or a close relative when the respondent has died (Subsection 5.4). All numbers and figures reported in this documentation are based on information from SHARE's Sample CTRL and Case CTRL as well as additional national gross sample information using the scientific release 9.0.0.

2.   Sampling frames and sampling designs in SHARE

The aim of the SHARE survey design is to be able to draw inferences about the population of people who are 50 years and older across countries by using probability-based sampling. This is a complex process since the samples in each country must do justice to national characteristics but at the same time be internationally comparable. In the ideal case, all countries included in SHARE would have a probability-based sample based on an official person register covering the population of interest. The availability of population registers that can be used as sampling frames varies a lot across countries, however, as do the regulations about who can or cannot access the registers and what information can be obtained from them. A key feature that any frame must fulfill in SHARE is the availability of reliable information on age. If this information is not available from a given sampling frame – as it is frequently the case when no population register with individual information is available – a screening procedure to identify the age of respondents has to be applied before starting fieldwork. In this case, we require using the Sample/Case CTRL software for screening the whole sample for age-eligibility. The necessity to have a screening procedure identifying persons of 50 years and older is a specific feature of SHARE: It can negatively affect the response rate obtained as it is an additional step for realizing an interview. As a result, it is difficult to compare response rates across countries in general. Nevertheless, when making these comparisons, researchers should at least point out country differences (e.g. screening), especially when referring to total response/retention rates (see below), as these also depend on changes in the composition of countries over time. This makes comparisons within SHARE challenging, and even more so when comparing rates across different surveys.

Table 1 provides an overview of the sampling frame types (with one line for each sampling frame when changes occurred over time) and indicates whether it contains age-related information or not. It also specifies the sampling unit and the wave at which a baseline/refreshment sample was drawn, as well as important sampling design features. The most recent sample refreshment was conducted in 2019 for use in Wave 8. Due to the stop of Wave 8 fieldwork because of the pandemic, most participating countries were unable to completely field their planned refreshment sample or could not even start it in the case of Finland, Portugal and Spain. Not finished refreshment samples thus have been continued in Wave 9. For the started refreshment samples in Wave 8, there were no individual units (with information on age) available in the Czech Republic, France, Israel and Latvia. Therefore, a screening procedure was necessary in these countries. In Belgium and Switzerland screening

for age-eligibility is no longer needed since Wave 4 and in Austria since Wave 8, as these countries achieved to use a population register with individual information on age from that time on.[2] Based on the available sampling frame, the most frequently used sampling design in the SHARE countries is a multi-stage stratified sampling design, i.e., the country is divided into several strata in a first step to ensure representativeness of different geographical areas within the country, to improve efficiency of the survey estimates, and to reduce the costs of the interview process. Within these strata, primary sampling units (PSUs, e.g., municipalities or zip codes) are usually drawn in a second step – often with a probability proportional to their size to give larger PSUs a larger probability of being sampled. If other relevant characteristics are available from the sampling frame – such as age and gender in the case of population registers – countries are advised to also use those for stratification. Finally, individuals or households/addresses can be drawn within the selected PSUs depending on the available information. In some countries (e.g., Denmark or Sweden since Wave 5) such a multi-stage sampling design is not needed as individuals can be drawn directly from the central population register (for more information on the specific characteristics of the used sampling designs, see Bergmann et al., 2019; Bergmann, 2024; Bergmann et al., 2017; De Luca et al., 2015).

---

[2] SHARE was the first survey that was allowed to use the Swiss population register, which is known to be of excellent quality.

Table 1: Sampling frames and sampling designs in SHARE

Note: I: Individual address (name + address); H: Households (last name + address); B: Building address (address without name).

[1] Including respondents who did the interview in a nursing home (mn024), lived in a nursing home during the last 12 months (hc029), received care or died in a nursing home (xt018_4, xt014), or when the type of building was recorded as a nursing home (ho036, iv010).

[2] Entries according to information provided by country teams and survey agencies.

[3] Data include nursing home respondents, although these may not be represented uniformly in the sampling frame.

All SHARE respondents who were interviewed in any previous wave (including non-responding partners) are part of the longitudinal sample. Additionally, refreshment samples are drawn regularly to i) maintain representation of the younger age-cohorts of the target population that were not age-eligible in previous waves and ii) compensate for the reduction in panel sample size due to attrition. Table 1 shows when refreshment samples were recruited or a new country joined SHARE for the first time with a baseline survey that would ultimately form the "first wave" panel sample for the next waves of the study. In practice, the decision to conduct a refreshment sample, as well as the sample size, depends heavily on the country-specific funding situation. As funding and sampling resources vary between participating countries, SHARE does not define a minimum net sample size. Instead, SHARE advises countries to maximize their net sample size within their budget, while carefully considering the representativeness of the entire sample.

Each country that draws a baseline or refreshment sample in a SHARE wave is initially required to provide a sample design form (SDF) containing a complete description of both the chosen sampling frame and the associated sampling design. Based on this form, the sampling proposal is evaluated and approved by the SHARE Central coordination team at the SHARE Berlin Institute (SBI) before the sample is drawn. The SDF is archived as a reference for the sampling information and the weighting design (see Bergmann et al., 2017; De Luca & Li Donni, 2024; De Luca et al., 2021; De Luca & Rossetti, 2019; De Luca et al., 2015 for a detailed discussion of the used weighting strategy). In addition, each country that draws a baseline or refreshment sample has to submit a gross sample template (GST). The GST must contain all selected households, the associated sampling frame information required to compute selection probabilities (e.g., household-level and population-level information about stratification and clustering), and household-level information about regional codes (NUTS and LAU). If applicable, it should also include additional auxiliary variables that could be used for ex-post compensation of non-sampling errors. Before calculating the weights, the SHARE Central coordination team carefully checks the coherence between the SDF and the GST.

3. Target population and eligibility criteria

The SHARE target population consists of all persons aged 50 years and older at the time of sampling who have their regular domicile in the respective SHARE country. Persons are excluded if they are incarcerated, hospitalized, or out of the country during the entire survey period, unable to speak the country's languages[3], could not be located due to errors in the sampling frame (e.g., non-existent address, vacant house), or have moved to an unknown address. In Wave 1, all age-eligible persons per sampled household (plus their partners, regardless of age) were selected for an interview. Since Wave 2, only one age-eligible person per household (plus partner, regardless of age) has been selected. All SHARE respondents who were interviewed in any previous wave are part of the longitudinal sample. If they have a new partner living in the household, the new partner is eligible for an interview as well (regardless of age). Age-eligible respondents who participated are traced and re-interviewed if they move within the country and end-of-life interviews are conducted if they decease. Younger partners, new partners, and partners who never participated in SHARE will not be traced if they move and are not eligible for an end-of-life interview. Persons living in nursing homes and other institutions for elderly are considered to be part of the target population investigated by SHARE but may not be equally well represented in all countries depending on the sampling frame coverage. As SHARE countries do not use specific sampling methods for these groups but include them as part of the general population sample, differences in sampling frames used across countries can lead to country-specific under-coverage of the nursing home population. Table 1 gives an overview of which countries include the institutionalized population in their baseline/refreshment samples (see also Schanze, 2017 for further information).

While these general eligibility criteria are determined through information provided during the individual SHARE interview, age-eligibility of an initially sampled household (i.e. at least one person aged 50 and older lives in the household) is determined through the very first part of the interview, the so-called coverscreen (CV). The CV is a brief interview on household composition before the actual interview starts. In practice, the CV is incomplete for non-responding households (i.e., households that were not contacted or refused to complete the CV) and thus does not allow assessing the age-eligibility of all sampled households. This problem, which is common to all countries, has different origins and consequences depending on the

---

[3] If a language is spoken by more than ten percent of the population in a certain country, the questionnaire is translated also into that language to include the language group in SHARE and to avoid under-coverage of important migrant groups (e.g., Russian in Estonia).

nature of the sampling frame adopted. In one group of countries (Austria since Wave 8, Belgium since Wave 4, Croatia, Denmark, Estonia, Finland, Germany, Hungary, Ireland, Israel, Italy, Luxembourg, Malta[4], the Netherlands, Poland, Portugal since Wave 8, Slovenia, Spain (including Girona), Sweden, and Switzerland since Wave 4), the sampling frame already contains information on the age of the sampled household member. For this first group of countries using a population or civil register, age-eligibility is determined directly from the information provided by the sampling frame. In another group of countries (Austria before Wave 8, Belgium before Wave 4, Bulgaria, Cyprus, Czech Republic, France, Greece, Latvia, Lithuania, Portugal before Wave 8, Romania, Slovakia, and Switzerland before Wave 4) the sampling frame does not contain information on age. For this second group of countries a screening phase before the actual interview is required to assess the age-eligibility of sampled households.

The American Association for Public Opinion Research provides guidelines for a final classification of sample units (see AAPOR, 2023) . On this basis, a variety of indicators on respondents' participation behavior (e.g., response rates) can be calculated, which are the focus of Section 4 and Section 5. Following these guidelines, the SHARE Sample CTRL that contains event history information for each contact event is used to classify the baseline/refreshment samples as well as the longitudinal samples of each country into three exhaustive and mutually exclusive main categories: (1) eligible households, (2) ineligible households, and (3) households of unknown eligibility (see Kneip et al., 2015 for further information on the hierarchical classification of contact events into household states).

The following figures show the size of the baseline/refreshment samples in each country[5] in all previous waves[6] and how they were composed regarding household eligibility status (i.e., at least one age-eligible respondent lives in the household). Absolute numbers can be found in the Appendix. In the mentioned countries with a sampling frame not containing any information on age, ineligibility can also be an outcome of the screening procedure. In addition, any form of screening non-response (non-contact, refusal, other non-response) led to classifying a

---

[4] Malta uses an electoral register with information on age. However, due to uncertainties in the available data, this information is double checked during the CV.

[5] Ireland is missing in Figure 2, because the necessary gross sample information is incomplete. Consequently, we have not calculated response rates for Ireland in the next section. In addition, the Netherlands are included in Figure 6 (Wave 6), although this sample was drawn from a national online sample (LISS panel) and conducted as an online experiment due to funding issues (see Das et al., 2017).

[6] In Wave 3, no new baseline or refreshment samples have been conducted.

household as having unknown eligibility[7]. Due to the lack of information on age from the sampling frame, the fraction of unknown eligibility is also highest in these countries. In countries where information on age is available from the sampling frame, households without any contact attempt are considered to be of unknown eligibility.

Figure 2: Baseline/refreshment samples in Wave 1 by classification of sample units

---
[7] In Austria, screening non-response leading to unknown eligibility and post-screening ineligibility could not be unambiguously separated from each other in Wave 4 (see Figure 4).

4.   Survey participation in the SHARE baseline and refreshment samples

With respect to the participatory behavior of respondents in their first (baseline/refreshment) interview, the following tables provide an overview of the number of successful interviews – both at the household level (Subsection 4.1) and the individual level (Subsection 4.2). There are several ways in which response rates can be calculated, depending on how cases of unknown eligibility are handled. They can be considered entirely eligible, partially eligible, or entirely ineligible. Following the AAPOR (2023) guidelines, these differences correspond to a number of slightly different response rates whose definitions are given below and which are presented in the next subsections.

$$RR1 = \frac{I}{(I+P) + (R+NC+O) + (UH+UR+UO)}$$

Response Rate 1 (RR1), or the minimum response rate, is the number of complete interviews (I) divided by the number of interviews (complete (I) plus partial (P)[8]) plus the number of non-interviews (refusal and break-off (R) plus non-contacts (NC) plus others (O)) plus all cases of unknown eligibility (unknown if housing unit exists (UH), unknown if there is an eligible respondent (UR), plus unknown, other (UO)). It represents the lower bound of the presented response rates.

$$RR3 = \frac{I}{(I+P) + (R+NC+O) + e(UH+UR+UO)}$$

Response Rate 3 (RR3) discounts the number of households with unknown eligibility by weighting it with the proportion of cases actually eligible. In SHARE, e is estimated as the fraction of eligible units among the cases with known eligibility, which assumes that the fraction of eligible units does not depend on whether the eligibility status is known or not. That this assumption might yield a biased overestimate of the eligibility rate is pointed out by Smith (2009), who argues that the proportion of eligible cases will fall given more attempts during fieldwork to establish the status of the remaining unknown cases (e.g., due to the fact that non-assigned telephone numbers with ringing tones cannot be resolved by more attempts). Consequently, also this version of calculating response rates might lead to an underestimation of the actual response rate.

---

[8] In SHARE, partial interviews are considered complete if all applicable modules including the interviewer observations (IV module) at the very end of the CAPI are conducted.

$$RR5 = \frac{I}{(I+P) + (R+NC+O)}$$

Response Rate 5 (RR5) is either a special case of RR3 in that it assumes that e=0 (i.e., that there are no eligible cases among the cases of unknown eligibility) or the rare case in which there are no cases of unknown eligibility. In this respect, RR5 represents the upper bound of the response rates presented.

The idea behind presenting not only one but several response rates is that countries with different sampling frames can be better compared as some need a screening procedure to determine the eligibility status while others need no initial screening. Generally, countries that need to screen for age-eligibility show lower response rates when cases of unknown eligibility are counted as eligible (RR1), because this constitutes an additional step for realizing an interview. The opposite is true with respect to RR5. In this scenario, response rates might be overestimated as the assumption of counting cases of unknown eligibility as entirely ineligible is not very plausible in countries that need to screen for age-eligibility. Therefore, for these countries RR1 as well as RR5 are inadequate – especially when response rates are compared between countries with different sampling frames. In this respect, counting cases of unknown eligibility as partially eligible (RR3) might be more suitable for comparisons of response rates between countries that need to screen for age-eligibility and those that have a priori information on age.

4.1 Household participation

The following tables show the number of households with at least one interview as well as the different household response rates of the baseline/refreshment samples by country. As can be seen, the variation across countries is considerable. It is mainly caused by differences in sampling frames and the need to screen for age-eligibility as mentioned above, but also by changes of survey agencies collecting the sample, their fieldwork procedures including legal restrictions with regard to refusal conversion, and the general survey climate (e.g., Kneip et al., 2015; Loosveldt & Joye, 2016). In addition, the sampling structure with respondents aged 50 years and older as well as frequently rather strict requirements regarding incentives and interviewer payment schemes that are not under the control of SHARE makes it very difficult to compare the presented rates with other (particularly non-European) surveys. Overall, most of the rates are in line with or even above the numbers of comparable surveys in the same period.

In Wave 8, fieldwork had to be suspended due to the pandemic in the middle of the data collection period, resulting in lower response rates until March 2020. Refreshment samples that were unfinished in Wave 8 were continued in Wave 9, when face-to-face interviewing could resume without risk to the vulnerable target population in SHARE. However, the ability to conduct face-to-face interviews varies greatly from country to country, with some still experiencing negative consequences for fieldwork performance due to new variants of the virus. Therefore, the response rates in Waves 8 and 9 cannot be directly compared to previous waves.

Table 2: Breakdown of all baseline/refreshment samples in Wave 1 by country

Country	Households with >=1 interview	Household response rate (RR1)[1]	Household response rate (RR3)[2]	Household response rate (RR5)[3]
Austria[a]	1165	36.5%	44.2%	51.8%
Belgium[a]	2519	34.3%	35.0%	40.3%
Denmark	1175	63.2%	63.3%	67.1%
France[a]	2053	58.2%	73.8%	97.5%
Germany	1992	57.6%	57.7%	58.2%
Greece[a]	1981	54.3%	59.5%	68.7%
Israel	1667	64.2%	64.2%	64.5%
Italy	1770	52.5%	52.7%	55.2%
Netherlands	1946	60.9%	60.9%	61.3%
Spain	1686	50.2%	50.2%	51.1%
Sweden	2136	53.7%	53.7%	53.9%
Switzerland[a]	706	32.1%	37.6%	44.0%
Total	*20796*	*52.2%*	*55.0%*	*60.1%*

Note: [a] Screening country.
Total response rates are calculated by considering the number of households with at least one interview in each country.
[1] RR1 is the number of complete interviews divided by the number of interviews (complete plus partial) plus the number of non-interviews plus all cases of unknown eligibility.
[2] RR3 estimates what proportion of cases of unknown eligibility is actually eligible by using the information about eligible and ineligible respondents from the sampling process.
[3] RR5 is either a special case of RR3 in that it assumes that there are no eligible cases among the cases of unknown eligibility or that there are no cases of unknown eligibility.

Table 3: Breakdown of all baseline/refreshment samples in Wave 2 by country

Country	Households with >=1 interview	Household response rate (RR1)[1]	Household response rate (RR3)[2]	Household response rate (RR5)[3]
Belgium[a]	190	42.1%	42.1%	42.1%
Czech Republic[a]	1874	40.7%	48.6%	71.9%
Denmark	860	65.2%	65.2%	65.2%
France[a]	635	53.0%	69.9%	95.3%
Germany	614	48.8%	48.8%	48.8%
Greece[a]	559	52.1%	54.3%	58.1%
Israel	271	77.9%	77.9%	78.6%
Italy	637	50.8%	50.8%	50.8%

Note: [a] Screening country. [b] Unfinished samples were continued after Covid-19.
Total response rates are calculated by considering the number of households with at least one interview in each country.

4.2 Individual participation

While for the above reported numbers households were considered as participating if at least one eligible household member was successfully interviewed, studying the response behavior of eligible individuals requires defining the response rate as the proportion of eligible individuals that actually respond. Again, several ways of computing individual response rates are possible, depending on how households with unknown eligibility are treated. In addition, the number of eligible individuals in households with an incomplete CV has to be determined. These households may or may not contain eligible individuals and different assumptions about their number therefore directly affect the response rate. As before, a fraction e is calculated, based on the assumption that the average number of eligible persons in a household with or without a complete CV is the same in each country. The estimated average number of eligible individuals per household is shown in each of the following tables together with the total number of individual interviews separated by gender and age groups. Individual response rates (RR1, RR3, and RR5) are then calculated using the formulas above and multiplying the respective denominator by the estimated number of eligible persons per household. Compared to the household response rates presented before, it can be seen that individual response rates are only marginally smaller. This indicates that in many cases interviewers managed to interview all eligible persons within a household.

Table 10: Breakdown of all baseline/refreshment samples in Wave 1 by country, sex, and age

Country	Total number of interviews	Male	Female	<50	50-64	65-74	75+	Estimated number of eligible persons per household	Individual response rate (RR1)	Individual response rate (RR3)	Individual response rate (RR5)	Within household individual response rate

Total response rates are calculated by taking into account the total number of interviews in each country.

5.   Survey participation in the SHARE longitudinal samples

Thus far, we have looked at survey participation of households and individuals in their first interview suppressing the longitudinal dimension of SHARE. This is the focus of the following section that investigates participation patterns of individuals who have been successfully interviewed before. To clearly distinguish these different aspects, we now use the terms retention and retention rate (instead of response rate) when it comes to the participation of individuals from the longitudinal sample. For a panel study like SHARE, its value is strongly determined by the long-term participation of panel members over waves. Only if persons can be observed multiple times as time passes by, it is possible to understand their individual ageing processes and to learn how respondents adapt to the changing environment over time. It is therefore of utmost importance to keep former respondents participating in the survey to exploit the full potential of SHARE regarding longitudinal analyses and conclusions. As can be seen, this goal is achieved quite well considering the difficulties SHARE is facing with respect to the sample structure of people aged 50 years and older, where natural mortality is a bigger issue than in most other surveys.

After several waves, various types of retention rates can be calculated conditional on previous participation that might differ between countries due to differences in the sample composition. Therefore, the longitudinal samples at the individual level in SHARE can be divided into four subsamples for better comparisons: *Subsample A* includes all respondents who participated in the previous wave of the SHARE survey.[9] *Subsample B* includes those respondents who ever participated in SHARE, but not in the previous wave, and live in a household where at least one household member participated in the previous wave. *Subsample C* includes respondents who ever participated, but not in the previous wave, and do not live in a household where at least one household member participated in the previous wave. Finally, *subsample D* includes missing and new partners who have not participated in SHARE before.

Based on these definitions, individual-level retention in the narrowest sense is given by the proportion of respondents retained in subsample A, ignoring potential future recovery (see Subsection 5.1). Additionally, retention in subsamples B and C informs about how well SHARE managed to get respondents back in the study who had already dropped out, which adds to panel

---

[9] Since Wave 7, subsample A is further divided into respondents who participated in the last SHARE wave and at least one earlier wave (subsample A1) and respondents who were newly recruited in the last SHARE wave from a baseline/refreshment sample and for whom the current wave is the second participation (subsample A2). Further information and more detailed splits between these subsamples can be found in Sand (2019).

retention. Participation behavior in subsample D is informative with respect to eligible persons in longitudinal households never interviewed before (i.e., either new sample members or eligible sample members for which reluctance to participate was overcome after refusals in previous waves) and adds to maintaining sample size. We thus present combined retention and recovery rates that include former respondents (Subsection 5.2) as well as new or missing partners (Subsection 5.3). While the latter focuses on the overall sample size development in SHARE, retention including former respondents in Subsection 5.2. is the most informative with respect to evaluating the success of maintaining panel respondents in the study. As an attempt to make the rates more comparable – both for the countries in SHARE that frequently show a different sample composition but also towards other surveys – we calculated annualized retention rates that take gaps as well as the biennial interval between waves in SHARE into account (see last column in tables of Subsections 5.2).

As a starting point, Figure 10 provides an overview of the development of the number of successful interviews in all SHARE samples over time, hence combining retention and recovery. The bars indicate the baseline (orange) and subsequent refreshment (different shades of grey) samples, while the change in the height of the bars illustrates the development of the various samples. The underlying numbers can be found in Table 48 in the Appendix. In addition, this table differentiates between main and end-of-live interviews that are also the focus of Subsection 5.4. As others (e.g., Blom & Schröder, 2011; Kneip et al., 2015) have shown before, attrition tends to be higher when panel members were approached for their first re-interview than in later waves. One consequence of rather high attrition rates is that the number of cases in the panel decreases, effectively reducing the power of longitudinal analyses. Furthermore, attrition from the panel might affect the sample composition, as certain groups of respondents might be more likely to drop out of the panel than others. However, previous analyses (Bergmann et al., 2022; Kneip et al., 2015) found only little if any evidence for selective attrition bias in SHARE. Only those in the oldest age group show a slightly higher probability of dropping out, which may actually be more indicative of natural mortality. Consequently, SHARE offers calibrated longitudinal weights that account for mortality of the original target population across waves (see Bergmann et al., 2017; De Luca & Li Donni, 2024; De Luca et al., 2021; De Luca & Rossetti, 2019 for details on the construction of these weights).

Figure 10: Sample development in SHARE

Legend:
- Baseline sample
- 1st Refreshment sample
- 2nd Refreshment sample
- 3rd Refreshment sample
- 4th Refreshment sample
- 5th Refreshment sample - Wave 8
- 5th Refreshment sample - Wave 9
5.1 Wave-to-wave retention excluding recovery

The following tables show the wave-to-wave participatory behavior of panel respondents who participated in the previous wave not distinguishing between main and end-of-life interviews. Recovered respondents who were brought back into the survey after missing one or more wave(s) are thus excluded here (but see Subsections 5.2 and 5.3 for retention rates including recovery). Missing entries are due to the fact that not all countries participated in every wave. Greece, for example, had dropped from SHARE in Wave 4 due to the economic crisis but could be recovered for participation in Wave 6. Accordingly, the retention rate reported for Greece in Wave 6 (Table 18, second last column) refers to respondents last participating in Wave 3. This has to be considered when comparing rates across countries: Since more time has passed between two consecutive participations, the realization of an interview is more difficult in this case compared to other countries. Gaps with respect to Israel (no participation in Waves 3 and 4), Hungary (no participation in Waves 5 and 6), Poland (no participation in Wave 5) and Portugal (no participation in Waves 5 and 8) have to be interpreted analogously.[10]

By taking a close look at the following tables, it can be seen that – similar to Section 4 on response rates – there is some variation in individual retention rates across countries. Again, a mixture of differences in sampling frames, sample composition (i.e., the proportion of newly recruited panel members via refreshment samples), fieldwork procedures, and legal restrictions between countries to approach respondents refusing in a previous wave are the main causes for this variation. The last aspect is particularly important, as some countries have strict data protection requirements that could complicate the future participation of the people interviewed. In Germany, for example, all respondents must be asked at the end of their first SHARE interview whether they agree in writing that their addresses can be stored for future re-contact. This strict legal requirement does not exist in this form in any other SHARE country and might explain the lower retention in Germany compared to other countries (see, e.g., Table 18). Another reason applies to the Swedish Wave 2 sample (see Table 19, first column). Here, the sample could not be entirely approached in Wave 3, which explains the low retention between Wave 2 and Wave 3. Fortunately, most of these cases could be recovered in Wave 4, which results in a much higher retention between Wave 3 and Wave 4 and its stabilization afterwards.

Moreover, the drop in retention between Wave 5 and Wave 6 in the Netherlands was due to severe cuts in funding that made it necessary to conduct the interviews in Wave 6 in a different

---

[10] Other gaps are due to the following reasons: Ireland only participated in Waves 2 and 3; Girona only participated until Wave 8.

mode (see Das et al., 2017 for more information). The only way to keep the panel dimension of SHARE in the Netherlands was hence a shift from face-to-face to online interviews. Despite the high internet penetration in the Netherlands, the numbers clearly point out the huge challenges of such a change for an ongoing face-to-face panel study of respondents 50+ when participating for the first time in SHARE. Insofar, the low retention rate between Wave 5 and Wave 6 in the Netherlands cannot be directly compared with the rates in other countries. Despite this exception, however, there is a clear and consistent increase in retention of long-term panel members until Wave 8 and the beginning of the Covid-19 crisis, suggesting a high overall panel stability that is comparable to other studies with even shorter time intervals between interviews.

The Covid-19 pandemic hit SHARE in the middle of Wave 8 fieldwork. To avoid putting the vulnerable group of older respondents at risk, it was decided to suspend face-to-face interviews and conduct telephone interviews with SHARE panel respondents in 2020 (SCS1) and 2021 (SCS2). This explains the lower retention rates in Wave 8 and the much higher retention rates in the first SHARE Corona Survey, which are based on the sample realized in Wave 8. However, the transitions between SCS1 and SCS2, SCS2 and Wave 9, and Wave 8 and Wave 9 illustrate high stability in retention rates across most countries, despite the necessary mode switch and the fact that the pandemic was still ongoing at the beginning of Wave 9 in some countries. Israel is an exception, indicating significant challenges with face-to-face interviewing due to the country-specific situation during Covid-19 as well as difficulties in recruiting interviewers in crisis areas.

Table 18: Wave-to-wave retention rates of all Wave 1 (2004) samples by country

Sweden	65.4%
Switzerland	61.7%
Total	*69.8%*

Note: Total response rates are calculated by taking into account the total number of interviews in each country.

5.2 Wave-to-wave retention including recovery of former respondents

In addition to the previous subsection, the following tables show the wave-to-wave participatory behavior of respondents irrespectively of their former participation patterns. Respondents who missed one or more wave(s) are hence included here, which explains why some rates are higher than 100 percent. Again, it can be seen that the wave-to-wave retention increases remarkably over time in nearly all countries resulting in a very high overall panel stability after several waves. It can also be seen, that considerably lower retention rates during the pandemic where followed by very high rates in Wave 9, pointing to mainly temporary dropout and successful recovery (see also Bergmann et al., 2022). In this respect, it should be noted that the transition to the first SHARE Corona Survey was based on Wave 7, due to the suspension of fieldwork and the high proportion of interviews that were not completed by the time the pandemic broke out during Wave 8. Interestingly, the Netherlands shows a very high response rate in the first SHARE Corona Survey, suggesting that many respondents who did not participate online returned when another mode was introduced (see, for example, the second column in Table 25 continued). Furthermore, the significant variation between countries regarding the transition between Waves 8 and 9 can be partially explained by differences in the status of fieldwork when face-to-face interviews had to be stopped due to the pandemic (catch-up effects). In addition, the same considerations as in Subsection 5.1 apply with respect to comparisons between countries. To account for these differences between countries and samples we also calculated annualized retention rates, which consider gaps and the biennial interval between waves in SHARE. With values ranging from 85 to 95 percent, the annualized retention rates demonstrate the continued high level of sample stability in SHARE.

Table 25: Wave-to-wave retention rates incl. recovery of all Wave 1 (2004) samples by country

Country	Retention plus recovery (Wave 1-2)	Retention plus recovery (Wave 2-3)	Retention plus recovery (Wave 3-4)	Retention plus recovery (Wave 4-5)	Retention plus recovery (Wave 5-6)	Retention plus recovery (Wave 6-7)	Retention plus recovery (Wave 7-8)

5.3 Wave-to-wave retention including recovery of former respondents and new/missing partners

SHARE explores not only the original samples in each participating country from the first wave on, but also household members that enter the survey at later points in time, for example, when eligible persons move into SHARE households or partners do not participate from the beginning. The following tables in this subsection hence present the wave-to-wave participatory behavior of respondents including recovery as well as new/missing partners and thus provide

additional information about the sample size development in SHARE. Again, retention stabilizes after few waves at a high level, indicating that the survey succeeds in keeping respondents participating over a remarkable long time despite their, on average, advanced age. Further, the same restrictions as in Subsection 5.1 should be considered when comparing rates across countries.

Table 32: Wave-to-wave retention rates incl. recovery and new/missing partners of all Wave 1 (2004) samples by country

Country	Retention plus recovery (Wave 1-2)	Retention plus recovery (Wave 2-3)	Retention plus recovery (Wave 3-4)	Retention plus recovery (Wave 4-5)	Retention plus recovery (Wave 5-6)	Retention plus recovery (Wave 6-7)

5.4 End-of-life interviews by the respondents' partner or a close relative

SHARE requests interviewers to confirm the death of a respondent by a proxy respondent. In case of decease, interviewers try to conduct an end-of-life interview, which mainly contains information on the circumstances of death like time and cause of death (including Covid-19 since the outbreak of the pandemic). Proxy respondents can be a family member, a household member, a neighbor or any other person of the closer social network of the deceased respondents. Table 39 shows the number of end-of-life interviews that have been conducted in each country so far as well as the percentage of end-of-life interviews that could be realized from all deceased persons, whose death is validated by a proxy-respondent. Overall, end-of-life interviews could be realized for about three out of four deceased panel participants. However, due to the lack of a national mortality register (or other frequently updated administrative records) in most European countries, we cannot ascertain the vital status of non-respondents who drop out of the SHARE sample because they do not consent to be re-interviewed or – despite all efforts of our interviewers – cannot successfully be re-contacted. We are trying to convince national statistical offices to generate data that are more accurate, but this is a long-term process. Until data from mortality registers or similar records are available, SHARE has to classify the vital status of non-respondents without any further information from a proxy as "unknown". As a consequence, the number of cases with unknown vital status is larger in SHARE than in other studies, where a central mortality register is available, such as the Health and Retirement Study (HRS) or the Household, Income and Labour Dynamics in Australia (HILDA) Survey.

Table 39: End-of-life interviews in Waves 1-9 by country

Country	Number of end-of-life interviews	Percentage of end-of-life interviews from validated deceased persons
Austria	1040	72.8%
Belgium	1235	65.0%
Bulgaria	180	70.3%
Croatia	459	80.1%
Cyprus	82	68.9%
Czech Republic	1544	78.1%
Denmark	1005	72.0%
Estonia	1959	81.2%
Finland	55	56.7%
France	977	56.2%
Germany	699	49.5%
Greece	1299	87.0%
Hungary	708	76.4%
Ireland	36	54.5%
Israel	896	88.0%
Italy	1431	78.7%
Latvia	152	75.6%
Lithuania	204	73.9%
Luxembourg	104	51.2%
Malta	81	80.2%
Netherlands	563	38.6%
Poland	1218	71.9%
Portugal	368	68.9%
Romania	319	83.9%
Slovakia	66	89.2%
Slovenia	895	73.7%
Spain	1915	77.8%
Sweden	1268	73.7%
Switzerland	496	70.7%
Total	*21254*	*73.6%*

Note: Average percentage of end-of-life interviews from validated deceased persons takes into account the number of conducted end-of-life interviews in each country sample.
